Chapter 1

Qubits

The computers we use today rely on classical information theory, which are based on **bits** (binary digits) which can represent a 0 or 1 state. These **classical computers** are equivalent to a Turing Machine in computational efficiency.

On a quantum computer the **qubit** (quantum bit) is the basic unit of information.

In labs, qubits have been implemented using photon polarization, electron spin, the ground/excited state of an atom in a cavity, and even defect centers in a diamond. In this paper, we will define a qubit as an abstracted mathematical object and expect that every real-world implementation follow the same rules.

Definition 1.0.1: A **qubit** is any quantum mechanical system which is associated with 2-dimensional complex Hilbert space \mathcal{H} known as the **state space** and follows the below principles:

- Principle of Superposition
- Principle of Entanglement
- Principle of Measurement
- Principle of Transformation

A given state of the system is completely described by a *unit vector* $|\psi\rangle$, which is called the **state vector** (or wave function) on the Hilbert Space

The principles in the above definition will be elaborated on in the upcoming sections.

Notation 1.0.2: Observe above that we have written the vector $\vec{\psi} \in \mathcal{H}$ as $|\psi\rangle$. This is the notation for a vector in Dirac's bra/ket notation, and is read **ket psi**

1.1 Superposition

Lemma 1.1.1 (Principle of Superposition): Suppose $|\psi\rangle$ and $|\sigma\rangle$ are two mutually orthogonal vectors in the state space \mathcal{H} of a quantum system, and $a, b \in \mathbb{C}$. Then $a|\psi\rangle + b|\sigma\rangle$ is a valid state vector of the quantum system when $a^2 + b^2 = 1$. The state of the system is completely defined by its state vector which is a unit vector in the systems' state space.

A given state of the system is completely described by a *unit vector* $|\psi\rangle$, which is called the **state vector** (or wave function) on the Hilbert Space. This leads to qubits being referred to as **two-state** quantum systems since its state is the linear combination of two orthogonal basis vectors. These orthogonal states act as the basis elements of the Hilbert space \mathcal{H} modelling the qubit.

When working with Hilbert spaces associated with quantum systems, we normally use *orthonormal bases*.

Definition 1.1.2: The **computational basis** for the two dimensional complex vector space \mathcal{H} is $\{|0\rangle, |1\rangle\}$ where $|0\rangle = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$ and $|1\rangle = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$

With respect to the computational basis $\{|0\rangle, |1\rangle\}$, the state of the qubit can be described as

$$|\psi\rangle = a|0\rangle + b|1\rangle = \begin{bmatrix} a \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ b \end{bmatrix} = \begin{bmatrix} a \\ b \end{bmatrix} \text{ where } a, b \in \mathbb{C} \text{ and } a^2 + b^2 = 1.$$

Another commonly used orthonormal basis for the Hilbert space \mathcal{H} modelling a qubit is the Hadamard Basis.

Definition 1.1.3: The **Hadamard Basis** for the two dimensional complex vector space \mathcal{H} is $\{|+\rangle, |-\rangle\}$ where

$$|+\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ 1 \end{bmatrix} \text{ and } |-\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

Lemma 1.1.4: Unit vectors equivalent upto multiplication by a complex number of modulus 1 represent the same state.

Consider $|\psi\rangle = a|0\rangle + b|1\rangle$ where $|a|^2 + |b|^2 = 1$ and $|\sigma\rangle = a'|0\rangle + b'|1\rangle$ where $|a'|^2 + |b'|^2 = 1$ and $a|0\rangle + b|1\rangle = c(a'|0\rangle + b'|1\rangle)$ where $c \in \mathbb{C}$ is a complex number of modulus 1. Then $|\psi\rangle$ and $|\sigma\rangle$ represent the same state.

The multiple c by which two vectors representing the same quantum state differ is called the **global phase**. Global phases are artefacts of the mathematical framework we are using and have no physical meaning.

1.2 Measurement

The principle of superposition might indicate that we can use the continuum state of single qubit to store an infinite amount of information. However, a principal of quantum mechanics states that we cannot interact with the qubit without fundamentally altering its state. To know the state stored in a qubit, we must perform a measurement which forces the state of the qubit to "collapse" into one of two *preferred states*.

A naive version principle of measurement for a single qubit is stated below. We will formalize this notion and generalize it to multiple qubits.

Lemma 1.2.1 (Principle of Measurement): Any measurement device that interacts with the qubit will be calibrated with a pair of orthonormal vectors called the **preferred basis**, say $\{|u\rangle, |v\rangle\}$. If the state of the qubit with respect to the preferred basis is $|\psi\rangle = a|u\rangle + b|v\rangle$, then measurement of the qubit will yield either $|u\rangle$ with a probability of $|a|^2$ or $|v\rangle$ with a probability $|b|^2$.

The process of measurement leads to the quantum state vector $|\psi\rangle$ undergoing a discontinuous change which leads to the collapse of the state vector onto one of the vectors in the preferred basis.

To formalize this notion, we have two main options: projection-valued measures (PVM) and positive-operator-valued measure (POVM). We will proceed to describe PVMs here.

Definition 1.2.2: An **observable** is a physically measurable quantity of a quantum system which is represented by a self-adjoint operator on the Hilbert space associated with the quantum system.

Lemma 1.2.3: The eigenvectors of an observable form an orthonormal basis for the Hilbert space.

Lemma 1.2.4: In a qubit represented by Hilbert space \mathcal{H} , the possible measurement values of an observable are given by the spectrum $\sigma(A)$ of the self adjoint operator A representing the observable.

The probability $p_\psi(\lambda)$ that a quantum system in the pure state $|\psi\rangle \in \mathcal{H}$ yields the eigenvalue λ of A upon measurement is given by the projection P_λ onto the eigenspace $\text{Eig}(A, \lambda)$ of λ as $p_\psi(\lambda) = \|P_\lambda |\psi\rangle\|^2$

Lemma 1.2.5 (Principle of Measurement): Any physical observable is associated with a self-adjoint operator \mathcal{A} on the Hilbert space \mathcal{H}_S . The possible outcome of a measurement of the observable \mathcal{A} is one of the eigenvalues of the operator \mathcal{A} .

Writing the eigenvalues equation, $\mathcal{A}|i\rangle = a_i|i\rangle$ where $|i\rangle$ is an orthonormal basis of eigenvectors of the operator \mathcal{A} , and $|\psi\rangle = \sum_i c_i |i\rangle$, then the probability that a measurement of the observable \mathcal{A} results in the outcome a_i is given by $p_i = |\langle i|\psi\rangle|^2 = |c_i|^2$

Definition 1.2.6: A **density operator** is a positive semi-definite operator on the Hilbert space whose trace is equal to 1.

Lemma 1.2.7: For each measurement that can be defined, the probability distribution over the outcomes of the measurement can be computed from the density operator as defined by Born's rule: $P(x_i) = \text{tr}(\Pi_i \rho)$ where ρ is the density operator and Π_i is the projection operator onto the baiss vector corresponding to the measurement outcome x_i .

Lemma 1.2.8: The expectation value of a quantum state ρ is $\langle A \rangle = \text{tr}(A\rho)$.

Definition 1.2.9: Let \mathcal{H} be a Hilbert space. We call states $|\psi_1\rangle, |\psi_2\rangle, \dots, |\psi_n\rangle \in \mathcal{H}$ perfectly distinguishable if there exists a measurement system $\{M_i\}_{i=1}^m$

with $m \geq n$ such that $\|M_j |\psi_1\rangle\|^2 = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$

Here *perfectly distinguishable* means that there is some experiment or experimental setup that can distinguish between these two states, atleast in theory.

Result 1.2.10: The states $|\psi_1\rangle, |\psi_2\rangle, \dots, |\psi_n\rangle$ are perfectly distinguishable if and only if they are orthogonal. This result is the reason we use orthogonal basis in quantum computing.

‘TODO: Refer Nielsen, Chuang

This property limits the amount of information that can be extracted from a qubit: a measurement yields atmost a single classical bit worth of information. In most cases, we also cannot make more than one measurement of original state of the qubit. On measurement, we have two possibilities, each corresponding to a probability of $|a|^2$ and $|b|^2$, then the total probability of the whole space will be $|a|^2 + |b|^2 = 1$, which is valid for unit vectors $|\psi\rangle = a|0\rangle + b|1\rangle$.

Notation 1.2.11: When $|\psi\rangle = a|0\rangle + b|1\rangle = \begin{bmatrix} a \\ b \end{bmatrix}$, then $\langle\psi|$ is the conjugate transpose of $|\psi\rangle$ and is read as **bra psi**, $\langle\psi| = [\bar{a} \quad \bar{b}]$

This lets us write the inner product for \mathcal{H} as: For any $|v\rangle = \begin{bmatrix} a \\ b \end{bmatrix}, |w\rangle =$

$\begin{bmatrix} c \\ d \end{bmatrix} \in \mathcal{H}$, the operation $\langle v|w\rangle = \langle v||w\rangle = [\bar{a} \quad \bar{b}] \begin{bmatrix} c \\ d \end{bmatrix} = \bar{a}c + \bar{b}d$

We will consider the inner product as being linear in the second variable and conjugate-linear in the first variable.

Remark 1.2.12: If $|\psi\rangle = \begin{bmatrix} a \\ b \end{bmatrix}$, then we can show $\langle 0|\psi\rangle = a$, $\langle 1|\psi\rangle = b$. Therefore we can write $|\psi\rangle = a|0\rangle + b|1\rangle = \langle 0|\psi\rangle|0\rangle + \langle 1|\psi\rangle|1\rangle$.

Remark 1.2.13: The standard inner product of the $|\psi\rangle = \begin{bmatrix} a \\ b \end{bmatrix}$ with itself in the Hilbert space \mathcal{H} can therefore be written as $\langle\psi|\psi\rangle = \langle\psi| |\psi\rangle = \begin{bmatrix} \bar{a} & \bar{b} \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix} = |a|^2 + |b|^2 = 1$

‘TODO: Proof that self-adjoint matrices represent measurement operators‘

‘TODO: Relation of POVM and matrices‘

Let \mathcal{H}_1 be an n -dimensional vector space with basis $\alpha = \{|a_1\rangle, |a_2\rangle, \dots, |a_n\rangle\}$ and \mathcal{H}_2 be an m -dimensional vector space with basis $\beta = \{|b_1\rangle, |b_2\rangle, \dots, |b_m\rangle\}$, then the tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2$ is an nm -dimensional space with basis elements of the form $|a_i\rangle \otimes |b_j\rangle$

Notation 1.2.14: In dirac’s bra/ket notation, the tensor product of $|v\rangle \in \mathcal{H}_1, |w\rangle \in \mathcal{H}_2$ is $|vw\rangle = |v\rangle|w\rangle = |v\rangle \otimes |w\rangle$

The tensor product is defined to satisfy the following properties:

1. $(|v_1\rangle + |v_2\rangle)|w\rangle = |v_1\rangle|w\rangle + |v_2\rangle|w\rangle$
2. $|v\rangle(|w_1\rangle + |w_2\rangle) = |v\rangle|w_1\rangle + |v\rangle|w_2\rangle$
3. $(a \cdot |v\rangle)|w\rangle = |v\rangle(a \cdot |w\rangle) = a \cdot (|v\rangle|w\rangle)$

Every element $|\sigma\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$ can be written as a superposition of elements of the basis $\{|a_i\rangle|b_j\rangle\}$ as $|\sigma\rangle = \alpha_{11}|a_1b_1\rangle + \alpha_{12}|a_1b_2\rangle + \dots + \alpha_{nm}|a_nb_m\rangle$.

Most elements $|\sigma\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$ *cannot* be decomposed to $|\sigma\rangle = |v\rangle|w\rangle$ where $v \in \mathcal{H}_1, w \in \mathcal{H}_2$. ‘TODO: Check proof‘

Here *perfectly distinguishable* means that there is some experiment or experimental setup that can distinguish between these two states, atleast in theory.

Definition 1.2.15: Let \mathcal{H} be a Hilbert space. We call states $|\psi_1\rangle, |\psi_2\rangle, \dots, |\psi_n\rangle \in \mathcal{H}$ perfectly distinguishable if there exists a measurement system $\{M_i\}_{i=1}^m$ with $m \geq n$ such that $\|M_j |\psi_1\rangle\|^2 = \begin{cases} 1 & \text{if } i = j \\ 0 & \text{if } i \neq j \end{cases}$

Result 1.2.16: The states $|\psi_1\rangle, |\psi_2\rangle, \dots, |\psi_n\rangle$ are perfectly distinguishable if and only if they are orthogonal. This result is the reason we use orthogonal basis in quantum computing.

Positive-Operator-Valued Measures (POVMs) are a further generalization of the Projection-Valued Measure (PVMs) and are described in the appendix.

1.3 Entanglement

As we have observed, a single qubit only gives us one classical bit worth of information. This equivalence diverges once we include *multiple* interacting qubits in the system. A system of n classical bits will have one degree of freedom for each bit, resulting in a state-space of n dimensions, i.e. classical systems are linear in n . In quantum systems, however, a system of n qubits will result in a state space of 2^n dimensions. This is because of the quantum property of *entanglement* which describes how quantum systems interact with each other.

Lemma 1.3.1 (Principle of Entanglement): When we have two qubits being treated as a combined system, the state space of the combined system is the tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2$ of the state spaces $\mathcal{H}_1, \mathcal{H}_2$ of the component qubit subsystems. If the first qubit is in state $|\psi\rangle$ and the second in state $|\sigma\rangle$, then the combined system of two interacting qubits is in state $|\psi\sigma\rangle = |\psi\rangle |\sigma\rangle$. Similarly, for a system of n qubits, the state space is the tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \dots \otimes \mathcal{H}_n$ of the state spaces of the n independent qubits.

The most natural basis for $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2$ is constructed from the tensor products of the basis vectors of \mathcal{H}_1 (say $\{|0\rangle_1, |1\rangle_1\}$) and of \mathcal{H}_2 (say $\{|0\rangle_2, |1\rangle_2\}$), then a basis for \mathcal{H} is given by $\{|0\rangle_1 |0\rangle_2, |0\rangle_1 |1\rangle_2, |1\rangle_1 |0\rangle_2, |1\rangle_1 |1\rangle_2\} = \{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$.

We will often this basis as $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\} = \{|0\rangle, |1\rangle, |2\rangle, |3\rangle\}$ when the context is unambiguous. So an arbitrary state $|\psi\rangle \in \mathcal{H}$ can be described as $|\psi\rangle = c_0 |00\rangle + c_1 |01\rangle + c_2 |10\rangle + c_3 |11\rangle = c_0 |0\rangle + c_1 |1\rangle + c_2 |2\rangle + c_3 |3\rangle$.

Definition 1.3.2: A state $|\psi\rangle$ is said to be **entangled** if it cannot be written as a simple tensor product of states $|v\rangle \in \mathcal{H}_1$ and $|w\rangle \in \mathcal{H}_2$. If we can write $|\psi\rangle = |v\rangle |w\rangle$, the state is said to be **seperable**.

Example 1.3.3: Consider the state $|\psi_1\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$. We can show this is entangled. ‘TODO‘

Example 1.3.4: Consider the state $|\psi_2\rangle = \frac{1}{\sqrt{2}}(|01\rangle + |11\rangle)$. We can show this is seperable since we can write $|\psi_2\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) \otimes |1\rangle$

Lemma 1.3.5: Most states are entangled.

Lemma 1.3.6: Tensor product of basis elements form a basis of the tensor space.

1.4 Transformation

Lemma 1.4.1 (Principle of Transformation): Isolated Quantum states evolve unitarily, i.e. for an isolated system there exists a unitary matrix U_t such that $|\psi_t\rangle = U_t |\psi_0\rangle$ where $|\psi_0\rangle$ is the starting state and $|\psi_t\rangle$ is the state at time t .

Theorem 1.4.2: Any change applied to a quantum state can be represented by a unitary matrix M .

Proof. The initial state of the quantum state is a unit and so is the result state. This means we require that the transformation applied to the unit vector $M |psi\rangle$ is a unit vector itself.

This will happen when $\langle M\psi | M\psi \rangle = 1$ for all quantum states $|\psi\rangle$
 $\implies \langle psi | M^\dagger M | \psi \rangle = 1 \implies M^\dagger M = I$ which is the condition for M being a unit vector. \square

Definition 1.4.3: An observable is a physically measurable quantity of a quantum system which is represented by a self-adjoint operator on a Hilbert space.

Definition 1.4.4: A matrix is said to be **unitary** if and only if one of the following conditions hold:

1. $U^\dagger U = I$
2. $UU^\dagger = I$
3. the columns of U are orthonormal vectors
4. the rows of U are orthonormal vectors

‘Alternate from Scherer‘

Definition 1.4.5: An operator U on H is called **unitary** if $\langle U\psi | U\phi \rangle = \langle \psi | \phi \rangle$ for all $|\psi\rangle, |\phi\rangle \in \mathcal{H}$

Lemma 1.4.6: The operator that takes $|a_1\rangle \rightarrow |b_1\rangle$ and $|a_2\rangle \rightarrow |b_2\rangle$ is obtained by the operation: $|b_1\rangle\langle b_1| + |b_2\rangle\langle b_2|$.

Lemma 1.4.7: Quantum gates have the same number of inputs and outputs.

Lemma 1.4.8: Quantum Gates are reversible.

Chapter 2

Gates

Proposition 2.0.1: Gates are described by unitary matrices.

Proof. Let M be a transformation of a quantum qubit state $|\psi\rangle$. Physics says that the evolution of an isolated quantum system is linear, so the transformation M can be described by a matrix.

For any state $|\psi\rangle$, $M|\psi\rangle$ has to be a unit vector.

If $M|\psi\rangle$ is a unit vector, the inner product with itself is 1.

$$\implies \langle (M|\psi\rangle) | (M|\psi\rangle) \rangle = 1$$

$$\implies \langle \psi | M^\dagger M | \psi \rangle = 1$$

$$\implies M^\dagger M = I \text{ where } I \text{ is the identity matrix}$$

$$\implies M \text{ is unitary}$$

□

Example 2.0.2: Verify that the Hadamard gate is unitary and find its eigenvalues, eigenvectors.

Since $UU^\dagger = I$, we can conclude that every unitary matrix is invertible. This leads to the following result:

Result 2.0.3: Only reversible gates can be implemented in quantum computing and any reversible gate has a quantum analog.

This shows us that the classical NOT gate has a quantum analog but NAND does not.

Any unitary 2×2 matrix is a valid gate but only a few are used in practice.

‘TODO Notation $| \rangle \langle |$ ‘

2.1 Gates on a single Qubit

Definition 2.1.1 (Pauli Gates): I, X, Y, Z are known as the Pauli gates and are defined as:

1. $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = |0\rangle \langle 0| + |1\rangle \langle 1|$
2. $X = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} = |1\rangle \langle 0| + |0\rangle \langle 1|$
3. $Y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} = i|1\rangle \langle 0| - i|0\rangle \langle 1|$
4. $Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} = |0\rangle \langle 0| - |1\rangle \langle 1|$

‘TODO: Effect of the Pauli Gates on the Bloch Sphere‘

Definition 2.1.2 (Hadamard Gate): The **Hadamard Gate** is the transformation $H : \mathcal{H} \rightarrow \mathcal{H}$ such that

$H|0\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) = |+\rangle$ $H|1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) = |-\rangle$. It is defined by the matrix $\frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = |0\rangle \langle +| + |1\rangle \langle -|$

The Hadamard gate allows us to obtain a superposition state.

Remark 2.1.3: The Hadamard gate is its own inverse.

$$H^2 = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix} = I$$

Remark 2.1.4: $H = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} = \frac{1}{\sqrt{2}} \left(\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \right) = \frac{1}{\sqrt{2}}(X + Z)$

Definition 2.1.5: The **z -Phase Gate** R_z defines a rotation about the z -axis by an angle θ on the Bloch sphere. ‘TODO: Bloch Sphere’

It is given by $R_z = \begin{bmatrix} 1 & 0 \\ 0 & e^{i\phi} \end{bmatrix} = |0\rangle\langle 0| + e^{i\phi} |1\rangle\langle 1|$

The **y -Phase Gate** defines a rotation about the y axis and is defined by

$$\begin{bmatrix} \cos \frac{\theta}{2} & -\sin \frac{\theta}{2} \\ \sin \frac{\theta}{2} & \cos \frac{\theta}{2} \end{bmatrix}$$

The **x -Phase Gate** defines a rotation about the x axis and is defined by

$$\begin{bmatrix} \cos \frac{\theta}{2} & -i \sin \frac{\theta}{2} \\ -i \sin \frac{\theta}{2} & \cos \frac{\theta}{2} \end{bmatrix}$$

2.2 Gates on Multiple Qubits

Definition 2.2.1: The **CNOT gate** is a gate that acts on 2 qubits which flips the second bit if the first bit is in the $|1\rangle$ state.

It is defined by the matrix $\text{CNOT} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{bmatrix} = |0\rangle\langle 0| \otimes I + |1\rangle\langle 1| \otimes X$

The CNOT gate allows us to obtain an entangled state.

Definition 2.2.2: The **Toffoli gate** is a gate that acts on 3 qubits that flips the third bit if the first two are in the $|1\rangle$ state.

Depending on the input the Toffoli gate can function as an AND, NOT and NAND gate. Since the NAND gate is universal, the Toffoli is as well. The Toffoli gate is also unitary which means it is a valid quantum gate. This shows that every classical circuit can be implemented as a quantum circuit.
